1. Foreword

Present document describes results of the sea area characterisation carried out at Taranto site, including a basin to be dredged to form a ship manoeuvring area for the proposed Taranto LGN Terminal (see figure 1).

Scope of work has been the collection of sediments samples to be submitted to analytical characterization in order to preliminary determine sediment quality and distribution of potential contamination, related to the future dredging of the area. It is worth to note that the official characterization project shall be submitted to the Ministry for Environment (Ministero dell'Ambiente).

The following paragraphs will describe:

- standard regulations taken into account in the analyses;
- the detailed program of site and laboratory investigations;
- results of chemical laboratory tests;
- very preliminary comments and recommendation for sediments dredging.

3. Environmental standard

In the following paragraphs regulations taken into account as reference are described.

Investigated soils have been collected from sea sediments; standard limits for these type of materials are established by the D.M. 367/03.

At present, the construction of a storage basin for sediments in the immediate vicinity of the on-shore area of the LNG Terminal is foreseen; in that case once that the above materials have been stored in a basin (on-shore, industrial use), the standard limits will be those indicated by D.M. 471/99 (much larger than the ones previously quoted).

As in this preliminary phase final use and destination of these materials is yet unknown, both limits relevant to D.M. 471/99 and D.M. 367/03 will be considered.

3.1 Ministerial Decree 471 dated 25 October 1999

For the environmental and qualitative characterisation of the areas under study, in agreement with the Customer, the environmental standard in force in Italy concerning the clean-up of contaminated sites was taken as reference. This standard is hereinafter briefly described.

Ministerial Decree 471 of 25th October 1999: Regulation containing criteria, procedures for soil and groundwater characterisation and clean-up, soil remediation goals based on land uses (industrial/commercial and residential/green) and groundwater remediation goals , in accordance to article 17 of decree 22 of 5th February 1997, and subsequent modifications and integrations (Official Gazette No. 293 of 15th December 1999).

This standard establishes the criteria, procedures and methods for the characterisation of the potentially polluted sites and states the acceptable limits for soil and groundwater contamination in relation to the land uses of the sites and the criteria for environmental remediation.

Enclosed table 1 shows the chemical acceptable maximum concentration limit values for analytes considered in this work.

Please note that "iron" is not included into the above regulation; however, its concentration has been checked because it could be useful when planning the way of "disposing of" or "treating" the above contaminated deposits.

3.2 Ministerial Decree n° 367 dated 6 november 2003

This standard establishes the acceptable limits for sediments and water in sea environment. In details, the reference quality standard for this specific investigation are collected in table 2.

4. Site characterisation

This chapter gives a detailed description of the investigation activities carried out at the dredging area during January 2005.

4.1 Details of investigation

To define sediments characterization within dredge basin an off shore soil investigation has been performed in the interesting area, consisting in:

- execution of n°15 boreholes (VC1, VC2,..., VC15), to 3 m depth homogeneously distributed in the dredging area;
- collection of soil samples (for a total of 135); as indicated in Ref. [2.2.1], sampling depths have been: from 10 to 30 cm, from 30 to 50 cm, from 100 to 120 cm, from 180 to 200 cm, and every 20 cm till the end (for a total of 9 samples);
- execution of chemical laboratory analyses on the totality of the soil samples collected with the detection of following analytes:
 - heavy metals (As, Cd, Fe, Hg, Ni, Cu, Pb, Zn Cr IV);
 - PAHs - Polycyclic Aromatic Hydrocarbons;
 - TPH- Total Petroleum Hydrocarbons (C>12 and C>12);
 - TOC - Total Organic Carbon.

Boreholes location is reported in the layout of investigation (Ref. [2.2.3]) and in enclosed figure 1.

Soil sampling has been carried out with a 3 m long "vibracorer" equipped at the bottom with a core retainer.

The vibracorer liner was made out of polycarbonate, ensured for no chemicals reaction.

The obtained core has been subdivided in single samples (as above specified) immediately after opening of the vibracorer liner, closing the material into an air-tight glass jar. The jars have been stored in a thermal container (with soft material around) for shipment to THEOLAB chemical laboratory (based at Volpiano (TO) - ITALY), in charge of analytical characterisation.

4.2 Analytical results

Results of the analyses carried out on the 135 soil samples collected at the site, are reported in three kind of tables (from '.A': VC1-VC2-VC3, ..., to '.E': VC13-VC14-VC15), showing detected analytical compound, used methods, Italian codes standard limits (both D.M. 471/99 and D.M. 367/03):

- 1) table 3: Chemical results - TOC and Total Petroleum Hydrocarbons;
- 2) table 4: Chemical results - Heavy Metal;
- 3) table 5: Chemical results - PAHs (Polycyclic Aromatic Hydrocarbons).

Comparing analytic results with code limit values, set by DM 471/99 for industrial/commercial soil, no samples exceed standard limits.

However, the sediment survey in question indicates the presence of some heavy metal: Arsenic, Cadmium, Chromium, Mercury, Nickel, Lead with concentration sometimes in excess of D.M. 367/99. To allow a better appreciation of local soil conditions, results in terms of the above substances are collected in table 6 (and in Drawing 1 - Attachment 1: Exceeding distribution map), where exceeding values only to D.M. 367/03 standard limits are highlighted (yellow coloured); reference has been made to measured percentages (i.e. neglecting the laboratory uncertainty attached to the method adopted for test execution).

5. Comments and Recommendations

All results of chemical tests have been by the laboratory reported in terms of a medium value plus or minus a method uncertainty (\pm MU, see Attachment 2: "Official Laboratory Certificates"); the comparison of medium values + MU with acceptable limits stated by D.M. 471/99 does not indicate any potential exceeding, except in 1 case (1 analyte per 1 sample) out of 2835 undertaken tests, referring to the 21 analytes (standard limits stated by Italian code) per 135 samples.

Adopting the same very on the safe side approach when comparing obtained results to limits established by D.M. 367/03, the number of exceeds could significantly increase, beyond the ones already evidenced in table 6 and graphically represented in Drawing 1 (see Attachment 1).

Table 6 shows also the resulting averages for all measured analytical compounds; it has to be stressed that in all cases they are lower than code limits.

As the materials will be dredged and stockpiled at prescribed locations for controls in relatively large volumes, it is possible that such mixing of soils will eliminate "peaks" of concentrations, so reducing exceeds.

In conclusion, from an "operational" point of view the encountered materials are to be considered as locally potentially contaminated when at sea bottom, but as "not contaminated" when on-shore.

This consideration could have significant consequences on the design of the on-shore retainment basin, at present under way, to be located in an area adjacent to the LNG (on-shore section) terminal. If the above basin can be considered an on-shore facility, acceptance limits from D.M. 471/99 are applicable and all the materials are fully acceptable from the contamination point of view. This will considerably simplify the needs for lateral, upwards and downwards containment of stored sediments; furthermore, the new reclaimed area could fully be used for future industrial expansion of the site.

The critical point could than mainly be the one of restitution to the sea of the water used to pump the marine sediments; the basin should be subdivided in several sections, decreasing as much as possible its velocity in order to increase the sedimentation of solids carried on by the flow.

For the dredging of the type of materials present within the area of interest, formed by sand and silty sands (as derived from logs and laboratory tests of boreholes BH25 and BH26, figure 1) the use of PNEUMA pumps is suggested. This tool is formed by a suction airlift pump and possesses the capability to excavate, extract or remove potentially contaminated bottom sediments while eliminating adverse environmental induced pollution effects.

The Pneuma Pump was developed by Pneuma S.r.l. Firenze Italy and modified by Voyageurs Maine Construction Company Ltd., Dorion, Québec to improve pumping efficiency and maintenance operations. The Pneuma system is primarily comprised of three cylinders adjoining shovels, three compressed air supply/exhaust pipes, a distributor unit, compressor, and a delivery pipeline. The system is based on hydrostatic pump principles.

A further advantage of the above technology is that the volume of water needed to remove and transport a unit volume of soils is form 1/3 to 1/4 of the one used by traditional dredgers, so significantly reducing the volumes of water to be cared of (and treated) on-shore.
